

- 12 *H. oregonensis* are split into three test groups and one control group. There are 3 replicates in each experimental group and 3 replicates in the control.
- Experimental groups are divided into a warm water treatment and a cold water treatment (standard Salish sea temperatures)
- One *C. maenas* individual is introduced in one warm water treatment group and one cold water treatment group.

Feeding

- Each week, a piece of frozen fish is thawed and weighed for mass.
- Each group is fed for 30 minutes
- The number and time spent feeding are recorded.

Resazurin

- Each week, after the feeding, each of the 12 crabs are placed in resazurin solution
- A T0, T1, and a T2 measurement are taken at time 0, 30 min, and 1 hour.
- Wells containing measurements are measured for florescence and recoded.

Protein Assay

- (Note: Week 3 only)
- Assay chemicals are mixed together and added to the tray. Hemolymph extract is added from the crab and then have it put through the machine to get the reading.

Checklist:

- ☐ Thawed the food?
- ☐ Weighed the food?
- ☐ Fed the crabs?
- ☐ Resazurin?
- ☐ (Week 3) Hemolymph extraction?
- ☐ (Week 3) Protein Assay?
